Summarising Meligethes aeneus

Pyrethroid resistance has been recorded in European populations of the pollen beetle (Brassicogthes aeneus; syn. Meligethes aeneus) since 1999, when it was first reported in Eastern France. The IRAC Coleoptera Working Group brings together expertise from agrochemical companies and independent researchers in order to monitor the development and spread of resistance in pollen beetles and other coleopteran pests of oilseed rape. Pyrethroid, neonicotinoid, organophosphate and indoxacarb susceptibility is measured by the use of insecticide coated glass vial assays. Results of the 2017 susceptibility monitoring program are presented in this poster. More details of the methods used in this survey can be found on the IRAC website (www.irac-online.org).

**Summary & Recommendations**

- In the majority of countries surveyed, pyrethroid resistant populations of pollen beetle dominate (> 60% are resistant).
- Samples of pollen beetle collected 2016 in Spain, Greece and Romania showed high levels of pyrethroid sensitivity, however no samples were collected from these countries in 2017.
- In 2017 less than 10% of pollen beetle populations (n=328) surveyed in Europe could be classified as pyrethroid susceptible.
- After an initial decline in the number of susceptible pollen beetle populations observed in Europe since the IRAC survey began in 2007, only small variations in the percentage of pyrethroid susceptible and resistant beetle populations have been observed since 2010.
- The majority of populations tested across Europe have remained susceptible to neonicotinoid insecticides. The percentage of populations with a lower sensitivity (<75% mortality) increased from 8% to 16%, however there was also an increase in the number of populations where less than 50% mortality was observed, with most populations originating in Poland.
- There is currently no evidence to suggest that the lower sensitivity observed in the survey correlates with a reduced performance of neonicotinoid containing insecticide products which are used under field conditions, however resistance management practice should be implemented to avoid further susceptibility decline.
- There was no evidence of changes in organophosphate and indoxacarb susceptibility observed in the European countries surveyed.
- In order to prevent further insecticide resistance development, it is recommended that insecticides with different modes of action are utilised in an effective resistance management program, dependent on local insecticide availability and national use guidelines. IRAC guidelines for resistance management in oilseed rape can be found on the IRAC website (www.irac-online.org).
- IRAC would like to thank all of those who contributed to the survey.

**Introduction and Background**

Pyrethroid resistance has been recorded in European populations of the pollen beetle (Brassicogthes aeneus; syn. Meligethes aeneus) since 1999, when it was first reported in Eastern France. The IRAC Coleoptera Working Group brings together expertise from agrochemical companies and independent researchers in order to monitor the susceptibility of pollen beetle populations in Europe. Changes in the pyrethroid susceptibility of pollen beetle populations in Europe between 2007 and 2017 suggest that in general pyrethroid resistant populations of pollen beetles have been on the increase at least until 2007. There are suggestions that the proportion of resistant populations have stabilised at about 85-90% since then. However, we have to consider that the countries and number of samples included in the surveys have varied during each year.

**Changes in pyrethroid susceptibility of pollen beetle populations in EU between 2007 - 2017**

Susceptibility surveys conducted in Europe between 2007 and 2017 suggest that in general pyrethroid resistant populations of pollen beetles have been on the increase at least until 2007. IRAC Working Group would like to thank all of those who contributed to the survey.
